# TradingPool Class
"""
This class models a basic liquidity pool in a decentralized exchange, similar to
↳those used in Uniswap.
It uses the constant product formula ( $x * y = k$ ) to manage the relationship
↳between two assets (ETH and TKN),
ensuring that their product remains constant during swaps.

Attributes:
    eth_reserves (float): Current amount of ETH in the pool.
    tkn_reserves (float): Current amount of TKN in the pool.
    k (float): The constant product of the reserves (eth_reserves *
↳tkn_reserves).
    lp_fees_eth (float): Accumulated ETH fees for liquidity providers.
    lp_fees_tkn (float): Accumulated TKN fees for liquidity providers.
    tkn_hard_cap (float): Maximum allowable TKN reserves in the pool to prevent
↳overflow.
"""
class TradingPool:
    def __init__(self, initial_eth, initial_tkn, tkn_hard_cap=10000):
        """
        Initializes the trading pool with initial reserves of ETH and TKN tokens.
        The product of the initial reserves (k) is calculated to enforce the
↳constant product formula.

        Parameters:
            initial_eth (float): Initial amount of ETH in the pool.
            initial_tkn (float): Initial amount of TKN in the pool.
            tkn_hard_cap (float): Maximum allowed TKN in the pool, default is 10000.
        """

        self.lp_fees_tkn = 0 # Initial liquidity provider fee balance in TKN
        self.tkn_hard_cap = tkn_hard_cap # Cap to prevent excessive TKN reserves

# =====
# SWAP
"""
This method handles swaps between ETH and TKN, adhering to the constant
↳product formula ( $x * y = k$ ).
It allows users to swap one asset for another while maintaining the balance
↳of the pool.
```

```

Parameters:
amount_eth (float): Amount of ETH to swap, default is 0.
amount_tkn (float): Amount of TKN to swap, default is 0.

Returns:
float: Amount of the opposite asset received in the swap, adjusted for
↳slippage.
"""

def swap(self, amount_eth=0, amount_tkn=0):
    """
    Executes a swap operation based on the constant product formula, with
    ↳slippage and fee considerations.

    Parameters:
    amount_eth (float): The amount of ETH being swapped for TKN. Defaults to
    ↳0 if TKN is provided.
    amount_tkn (float): The amount of TKN being swapped for ETH. Defaults to
    ↳0 if ETH is provided.

    Returns:
    float: The amount of the opposite asset obtained from the swap, after
    ↳slippage and fees.
    """

12. Strategy-Specific Logic Errors (Hardest Fix)
```

Issue: Some strategies may have logic that is not performing as intended, leading to unexpected results or ineffective trades.

Correction: Conduct a thorough review of each strategy's logic to ensure it aligns with its intended behavior. For example, Dove should consistently manage its risk without depleting its ETH, and Bull should maintain a feasible balance.

Likely Function(s):

```
Strategy.execute_trade()
Strategy.check_triggers()
Strategy.manage_balance()
```

lets get back to the strategies, lets treat this like a moba where we have a goal, the goal of the game is to use a strategy to acquire USD via trading tkn and eth. these are the gods/champions of the moba the strategies. each strategy is nash equilibrium cannot change and they cannot be over tuned.

analyze these results as an expert defi strategist and data analyst to check for accuracy of trades and results. this is a game theory experiment, where each participants strategy is to acquire the most usd as possible based on a given strategy in nash equilibrium. analyze the results are these results accurate? the experiment is based on a univ2 initiation liquidity event. the strategies are named by what they are supposed to do, are they accurately reflecting this? bear should be bear, bull should be bull, DCA should hold no token cause using all eth to buy, harvester gets in early and then just harvests eth from tkn, snipers go in early snipe supply and leave once in profit and dont interact with tkn any more, sniper 2 is the same but lagging. evaluate the strategies and the expected results. at this stage i want to complete the code so we can focus on the results but we are doing our last round of reviews to check codes based on the results we have. what other errors based on the results can you spot?

'''

as possible based on a given strategy in nash equilibrium. analyze the results are these results accurate? the experiment is based on a univ2 initiation liquidity event. the strategies are named by what they are supposed to do, are they accurately reflecting this? bear should be bear, bull should be bull, DCA should hold no token cause using all eth to buy, harvester gets in early and then just harvests eth from tkn, snipers go in early snipe supply and leave once in profit and dont interact with tkn any more, sniper 2 is the same but lagging. evaluate the strategies and the expected results. at this stage i want to complete the code so we can focus on the results but we are doing our last round of reviews to check codes based on the results we have. what other errors based on the results can you spot?\n\n \n'

[]:

[1620]:

Sniper1 and Sniper2:

Expected Behavior:

*Sniper1: Should enter early, acquire a large TKN position at a low price, and
→exit once profitable.*

Sniper2: Similar to Sniper1 but with a delayed entry.

Observed Behavior:

*Sniper1 acquired a significant amount of TKN early but didn't sell it, leading
→to a substantial unrealized loss.*

*Sniper2 entered the market late, bought a smaller amount of TKN, and also did
→not sell.*

Issues:

*Neither sniper strategy sold their TKN positions after buying, which contradicts
→the expectation that they would "snipe" and exit upon reaching a profitable
→point.*

Fix:

*Code Adjustment: Implement a sell condition based on a predefined profit margin.
→After acquiring TKN, the strategy should monitor the price and sell once a
→profit threshold (e.g., 10-20% gain) is reached.*

Bull:

Expected Behavior:

*The Bull strategy should aggressively buy TKN as prices fluctuate, aiming to
→accumulate as much TKN as possible. However, it should also be ready to sell
→if the market trends upward, maximizing profits.*

Observed Behavior:

The Bull strategy consistently bought TKN, but the final ROI is highly negative.

Issues:

*The strategy overextended by depleting its ETH balance without considering
→market trends, leading to a significant loss.*

Fix:

Code Adjustment: Implement a strategy where Bull initially acquires TKN, but
→with conditions to sell when a certain profit margin is reached, similar to
→the Sniper strategy but with more aggressive entry points. Introduce risk
→management controls to limit ETH expenditure, such as a cap on ETH usage per
→trade or a mechanism to stop buying when prices trend downwards significantly.

Bear:

Expected Behavior:

The Bear strategy should be cautious, acquiring a small amount of TKN at
→carefully chosen points (e.g., when volatility is low or prices are perceived
→to be at a peak) and then selling it when bearish signals (e.g., moving
→average crossover or significant price drops) appear.

Observed Behavior:

The Bear strategy didn't sell any TKN, resulting in no trades and a flat ROI.

Issues:

The strategy failed to acquire TKN, leading to no opportunities for selling or
→executing a bearish strategy.

Fix:

Code Adjustment: Implement a strategy where Bear acquires a small amount of TKN
→under specific conditions (e.g., low volatility) and sells when bearish
→signals appear. This aligns with the opposite of the Bull strategy, where Bear
→is defensive and looks to capitalize on downturns after acquiring TKN.

DCA (Dollar-Cost Averaging):

Expected Behavior:

The DCA strategy should periodically buy TKN in small increments to average the
→purchase price over time.

Observed Behavior:

The DCA strategy accumulated TKN over time but ended with a negative ROI.

Issues:

The strategy correctly followed its DCA logic but suffered from buying during a
→generally declining market.

Fix:

Strategy Enhancement: Consider adding an option to pause DCA purchases during
→sharp market downturns to avoid consistently buying into losses. Implement a
→trigger to resume DCA purchases when market conditions stabilize or improve.

Harvester:

Expected Behavior:

The Harvester should get in early, buy TKN, and then regularly sell small
→portions as prices rise, harvesting profits.

Observed Behavior:

The Harvester strategy performed well with a positive ROI, reflecting expected
→behavior.

Issues:

None.

Fix:
None Needed: The Harvester strategy is functioning correctly.
Dove:

Expected Behavior:
The Dove should be conservative, focusing on maintaining its initial capital.
Observed Behavior:
The Dove strategy made no trades, resulting in a flat ROI.
Issues:
None, as it preserved capital as expected.
Fix:
None Needed: The Dove strategy is functioning correctly.
Hawk:

Expected Behavior:
The Hawk should be aggressive, entering and exiting trades quickly to capitalize
→ on short-term price movements.
Observed Behavior:
The Hawk strategy performed exceptionally well, achieving a high ROI.
Issues:
None.
Fix:
None Needed: The Hawk strategy is functioning correctly.

However, it should also be ready to sell if the market trends upward, maximizing profits.\nObserved Behavior:\nThe Bull strategy consistently bought TKN, but the final ROI is highly negative.\nIssues:\nThe strategy overextended by depleting its ETH balance without considering market trends, leading to a significant loss.\nFix:\nCode Adjustment: Implement a strategy where Bull initially acquires TKN, but with conditions to sell when a certain profit margin is reached, similar to the Sniper strategy but with more aggressive entry points. Introduce risk management controls to limit ETH expenditure, such as a cap on ETH usage per trade or a mechanism to stop buying

when prices trend downwards significantly.\nBear:\n\nExpected Behavior:\nThe Bear strategy should be cautious, acquiring a small amount of TKN at carefully chosen points (e.g., when volatility is low or prices are perceived to be at a peak) and then selling it when bearish signals (e.g., moving average crossover or significant price drops) appear.\nObserved Behavior:\nThe Bear strategy didn't sell any TKN, resulting in no trades and a flat ROI.\nIssues:\nThe strategy failed to acquire TKN, leading to no opportunities for selling or executing a bearish strategy.\nFix:\nCode Adjustment: Implement a strategy where Bear acquires a small amount of TKN under specific conditions (e.g., low volatility) and sells when bearish signals appear. This aligns with the opposite of the Bull strategy, where Bear is defensive and looks to capitalize on downturns after acquiring TKN.\nDCA (Dollar-Cost Averaging):\n\nExpected Behavior:\nThe DCA strategy should periodically buy TKN in small increments to average the purchase price over time.\nObserved Behavior:\nThe DCA strategy accumulated TKN over time but ended with a negative ROI.\nIssues:\nThe strategy correctly followed its DCA logic but suffered from buying during a generally declining market.\nFix:\nStrategy Enhancement: Consider adding an option to pause DCA purchases during sharp market downturns to avoid consistently buying into losses. Implement a trigger to resume DCA purchases when market conditions stabilize or improve.\nHarvester:\n\nExpected Behavior:\nThe Harvester should get in early, buy TKN, and then regularly sell small portions as prices rise, harvesting profits.\nObserved Behavior:\nThe Harvester strategy performed well with a positive ROI, reflecting expected behavior.\nIssues:\nNone.\nFix:\nNone Needed: The Harvester strategy is functioning correctly.\nDove:\n\nExpected Behavior:\nThe Dove should be conservative, focusing on maintaining its initial capital.\nObserved Behavior:\nThe Dove strategy made no trades, resulting in a flat ROI.\nIssues:\nNone, as it preserved capital as expected.\nFix:\nNone Needed: The Dove strategy is functioning correctly.\nHawk:\n\nExpected Behavior:\nThe Hawk should be aggressive, entering and exiting trades quickly to capitalize on short-term price movements.\nObserved Behavior:\nThe Hawk strategy performed exceptionally well, achieving a high ROI.\nIssues:\nNone.\nFix:\nNone Needed: The Hawk strategy is functioning correctly.\n\n'

[1621]:

It seems that the Sniper strategies might be sniping too much of the token (TKN)□
→supply early on, which could be contributing to the issue where they end up□
→holding large amounts of TKN instead of converting it back to ETH as intended.□
→Here's a deeper analysis of why this might be happening:

Potential Issues with the Sniper Strategies

Over-Accumulation of TKN:

The Sniper strategies might be buying a substantial amount of TKN when the pool□
→is still small, significantly impacting the pool's reserves. This large□
→purchase can cause a steep increase in the TKN price, which then makes it□
→difficult for the strategy to find a profitable exit point because the pool□
→dynamics have changed drastically.

Result: The Sniper strategies hold a significant amount of TKN, but due to the□
→large price impact and the nature of the constant product formula, the price□
→does not increase enough afterward to meet the profit targets, leaving the□
→strategies stuck with TKN.

Unrealistic Price Impact Assumptions:

The Uniswap-like price impact calculation in your TradingPool class might not be□
→accurately reflecting how large trades would affect the market in a real-world□
→scenario. If the price impact is underestimated, the strategies might think□
→they can buy and sell large amounts of TKN without much slippage, leading to□
→unrealistic trading behavior.

Impact: This could mean that after the Sniper strategies purchase a large□
→portion of TKN, they face a much worse market condition than anticipated,□
→making it hard to sell off their holdings at a profit.

Adjustments to Consider

Limit the Amount of TKN Purchased:

To prevent the Sniper strategies from over-accumulating TKN, you could introduce□
→a cap on the percentage of TKN they can purchase in a single transaction. This□
→would reduce the immediate price impact and help maintain a more stable market□
→for subsequent trades.

Implementation: Introduce logic in the Sniper1Strategy and Sniper2Strategy□
→classes to limit the amount of TKN purchased to, for example, 10-20% of the□
→pool's TKN reserves.

Refine Price Impact Calculation:

Improve the calculate_price_impact method to better simulate realistic market□
→conditions. This might involve introducing more sophisticated slippage models□
→or using a larger slippage factor to account for the impact of large trades□
→more accurately.

Example: Increase the slippage factor in the swap method or use a dynamic□
→slippage model that increases with trade size.

Adjust Profit Targets:

As previously discussed, lowering the profit targets might help the Sniper
→ strategies find more opportunities to exit their positions. Given that the
→ strategies might be dealing with less favorable market conditions after their
→ large initial buys, a smaller profit margin could be more achievable.

Suggestion: Consider lowering the target profit from 10% to something like 5% or
→ even 3%.

Simulate Real-World Liquidity:

If possible, model the liquidity pool more closely after real-world conditions,
→ where large purchases dramatically increase slippage, and subsequent price
→ movements are less predictable. This would give a more accurate reflection of
→ how such strategies would perform in practice.

Approach: Introduce liquidity shocks or external market influences in the
→ simulation to mimic real-world trading environments.

Conclusion

The issue with the Sniper strategies appears to be twofold: they are buying too
→ much of the supply at once, which is distorting the market, and the price
→ impact model may not be accurately representing the consequences of such large
→ trades. By limiting the amount of TKN purchased, refining the price impact
→ calculations, and adjusting profit targets, you can likely get the Sniper
→ strategies to behave more realistically and avoid ending up with large,
→ unsellable TKN holdings.
